WHITE PAPER · INVESTORS & PARTNERS

A private, on-chain reservation primitive

One trusted source of truth for *who reserved what* — fed to many mutually-distrusting sales channels, without putting prices, terms, or personal data on-chain.

HONEST-STAGE STATEMENT

VRX is early. The contract runs on NEAR testnet and a seeded sandbox is live, but the network is **pre-revenue** and carries no production traction. This document describes a built primitive and a revenue *model* by design — not realised numbers. Where something is not yet live it is labelled **in progress / planned**. The paper stands on the truth of what exists.

EXECUTIVE SUMMARY

The thesis, in one page

VRX is a reservation primitive: a callable NEAR smart contract that records *who reserved what*, paired with a private off-chain portal that carries everything the chain must not — identities, prices, specifications and deal terms. Its market is any business that sells unique, non-substitutable inventory through channels that do not trust one another.

When each item is one-of-a-kind — a specific apartment, a specific pedigree animal, a specific machine — double-booking it across channels is not an inconvenience, it is a breached contract. Yet the tools that could give everyone a shared answer all fail the confidentiality test: a shared database or CRM centralizes trust in one vendor and leaks who is buying what at what price; a naïve public-chain listing leaks the very terms that make a deal confidential, forever. The market has had to choose between *shared truth* and *privacy*. VRX refuses the trade-off.

> **THE DESIGN ANSWER — AND THE MOAT**
>
> VRX enforces a strict **split**. The chain holds only opaque hashes and neutral account ids: it proves *that* a reservation exists and *who* holds it, and nothing else. The meaning — the *what*, the *how-much*, the *with-whom* — lives off-chain under server-side authorization and field-level masking. Layered on top is a **vetted operator network** and an owned forensic/provenance capability. The moat is not a faster database; it is the discipline of what is never written to the ledger at all, plus the human-vetting layer and IP others have not built.

WHAT'S BUILT	On-chain reservation / hold / exclusive / attestation registry (live on NEAR testnet); role-scoped portal; booking funnel; $VRX credit ledger; provenance-stamped imagery.
BEACHHEAD	Off-plan real estate — the sharpest version of the problem and the working proof.
EXPANSION	The contract never "knows" it is real estate — every reference is an opaque hash — so the same primitive serves cars, equipment, art, livestock, event slots.
REVENUE MODEL	Design-stage: watchlist / network access, commission anchoring, and a deposit / settlement rail. No realised revenue yet.
POSTURE	VRX facilitates and seals; it does not adjudicate disputes or warrant enforceability.

Status language throughout is honest: **built** means it runs today; **in progress / planned** means designed or partially built but not yet usable as described. The live demo is a seeded *sandbox* — write actions are simulated; the contract itself runs for real on NEAR testnet.

SECTION 1 · THE MARKET PROBLEM

Selling the unique, through channels that distrust each other

A whole class of high-value commerce shares one shape: scarce, identified inventory sold by an owner through many intermediaries who compete with one another. The existing toolchain breaks on it in three compounding ways — each with a direct cost.

Failure 1 — double-booking a unique thing

When inventory is fungible (seats, generic SKUs) an oversell is an inconvenience you reconcile later. When each item is unique, two channels reserving "312" at once is a hard conflict: one buyer must be told the thing they were promised is gone. In off-plan property that can mean a lost sale, a damaged agency relationship, and legal exposure on a signed reservation. The market needs **one authoritative answer** to "is this exact unit still available?" that every channel reads the same way, in real time — and no shared spreadsheet or per-agency portal delivers it across parties who will not share a database.

Failure 2 — privacy leakage

The naïve fixes leak. A shared spreadsheet or a single vendor database exposes who is buying what, at what price, through whom — to the vendor and often to rival channels. Putting the registry on a public blockchain is worse: now prices, parties and terms are world-readable forever. The commercially-sensitive and personal details of a deal are exactly what must *not* be shared to get the shared truth. For a developer, a leaked price list or buyer book is a competitive and regulatory liability, not a footnote.

Failure 3 — circumvention / disintermediation

A channel that learns the end-buyer and the operator can be tempted to cut the introducer out and deal direct — the commission disappears and the relationship that generated the lead is destroyed. The obvious counter-measure, hiding the buyer's identity until a deal is firm, is itself a privacy problem, and it must be reconciled with the operator's legitimate need to confirm a booking. The money and the trust are on the same seam.

> **THE TENSION IN ONE LINE**
>
> Everyone needs to agree on *the same reservation state*, while almost no one is entitled to see *the same reservation details*. A single store that satisfies the first requirement usually violates the second. VRX exists to hold both at once — and that gap is the market it addresses.

SECTION 1 · THE MARKET PROBLEM

Who feels it, and what it costs

Off-plan real estate is the sharpest case and VRX's beachhead; the same shape recurs across every market where inventory is scarce, identified, and sold through intermediaries.

The beachhead: multi-agency off-plan property

A developer releases limited units to multiple agencies, each with multiple agents, selling to buyers who must stay confidential — with deposits, commissions and completion terms attached. Every failure above is routine there: agencies double-book the same unit; price lists and buyer identities leak between rivals; agents and developers each fear being cut out of the commission. Today the industry papers over this with manual reconciliation, phone-call availability checks, and trust that does not scale past a handful of relationships.

Where the same shape recurs

MARKET	THE NON-SUBSTITUTABLE UNIT	THE DISTRUSTING CHANNELS
Off-plan / resale property	A specific unit, floor, view	Multiple agencies & agents, in-house desk
High-value vehicles	A specific VIN / spec / allocation	Dealers, brokers, allocation holders
Equipment & machinery	A specific serial / configured asset	Distributors, resellers, finance partners
Art & collectibles	A specific work / lot	Galleries, dealers, private intermediaries
Pedigree livestock	A specific animal / lineage	Breeders, agents, buyers
Event / venue slots	A specific date / space	Promoters, agencies, planners

WHY THIS GENERALISES CLEANLY

The contract does not model "apartment" or "car" — it models availability and holds over opaque keys it cannot read. That is a deliberate architectural choice (not an afterthought): the same deployed primitive serves every row above without a rewrite. Real estate proves it; the expansion path is a configuration and go-to-market question, not a re-engineering one.

A note on market sizing: these are large, established markets, but VRX makes no claim to a specific TAM figure in this document. The honest framing is qualitative — the problem is real, recurrent, and under-served by existing tooling. Any quantification would be invented, and VRX does not invent numbers.

SECTION 2

What VRX is

A callable NEAR smart contract — the reservation and hold registry — plus an off-chain portal: the role-scoped apps each participant uses. Together they are the reservation primitive.

The primitive, precisely

VRX records reservations over **non-substitutable** inventory. Its on-chain state is deliberately thin: a unit is `open`, on `hold`, `closed`, or `done`; a claim is open, accepted, declined, or confirmed; an exclusive window is held by one agency or it is not. Everything that would identify the unit, the buyer, the price or the terms is an opaque hash. The contract does not model "apartment" or "car" — it models availability and holds over keys it cannot read.

> **312 ≠ 311**
>
> Value in this system scales with the worth of the *specific* reserved item. The primitive's whole reason to exist is that substituting one unit for another is not acceptable — so the registry tracks each unit individually and a hold on one is never a hold on another. This is why the addressable value per transaction is high: these are not low-ticket bookings.

The four pillars, wrapped in vetting

The product is organised as four pillars, bound together by vetting and connected through the roles:

PILLAR	WHAT IT IS	STATUS
Availability	The foundation — what inventory exists and is open.	**built**
Communications	Availability made useful: clearly conveyed to the market, with channels + change-notice.	**built**
Payments	Communication turned into action — deposits, settlement projection (on-rail settlement planned).	**built / rail planned**
Accounting	Every payment tracked and accounted for (two-sided attestation ledger; VRX does not move money in-app).	**built**

Vetting ties the four together: VRX vets the whole system — every state, every step — so participants who do not trust each other can transact on one shared truth. Vetting is human-led (see §5); the chain only anchors the *fact and version* of a sign-off, never its contents. That vetting layer is both a trust mechanism and a business: it is what Vetted Realty operates.

SECTION 2.5 · COMPETITIVE LANDSCAPE

Why nothing in the market does this

Stated plainly, not boastfully — the moat is a design choice others have not made, not a claim of being uniquely clever. Each existing approach gives you one half of what the problem needs and pays for it with the other half.

Three existing approaches, and where each leaks

APPROACH	GIVES YOU	WHAT IT COSTS
Generic booking / CRM software	A shared calendar and pipeline.	Centralizes trust in one vendor's database; the vendor (and often rival channels) can see who buys what at what price. No independently-provable record; the operator still owns the single point of truth and failure.
Naïve on-chain listing	A tamper-evident, independently-verifiable record.	Publishes prices, parties and terms to the world forever. The confidentiality that makes a deal a deal is destroyed to gain the shared truth.
Point-to-point / off-platform deals	Privacy by obscurity.	No shared availability, so double-booking and circumvention are endemic; no neutral record when a dispute arises.

VRX'S POSITION

VRX takes the tamper-evident, independently-verifiable record from the on-chain approach and the confidentiality from the off-platform approach, and reconciles them with a **split**: the chain carries proof-of-state over opaque keys; a private, access-controlled off-chain layer carries the meaning. No incumbent in the booking / CRM space is built this way, and no generic "put it on-chain" project solves the confidentiality half. VRX sits in the gap between them on purpose.

Honest limits of the claim

- ✓ The off-chain layer's confidentiality rests on **server-side authorization**, not cryptography — VRX must be trusted to run it correctly. A standing security/privacy audit is how that trust is made checkable, and it is a submittable artifact to any partner who asks.
- ✓ The on-chain opacity is absolute by construction, but it only protects what lives on-chain; a leak, if it happened, would come from the off-chain layer — which is where almost all the engineering attention goes.
- ✓ VRX is not the only system that splits on/off chain. Its specific, defensible contribution is the reservation-primitive framing, the vetted operator network, and the owned provenance/forensic layer — not the generic idea of anchoring a hash.

SECTION 2.5 · COMPETITIVE LANDSCAPE

The moat, component by component

A defensible position in this category is not one feature; it is the compounding of four things that are each individually buildable but collectively hard to assemble and harder to copy credibly.

1 — The on/off-chain split as a discipline, not a toggle

The hardest part of the design is restraint: deciding what is *never* written to the chain. That discipline runs through every surface and every migration of the contract's state schema. A competitor cannot bolt it on later — retrofitting confidentiality onto a system that already leaks terms means rebuilding it. VRX started from this constraint, so the whole architecture is shaped by it.

2 — Human vetting as the trust anchor

Mutually-distrusting parties transact on one shared truth only because a trusted entity vets who enters the network and anchors the fact of each sign-off. That vetting is human-led and operated as a business. It is the part of the system that cannot be replaced by code alone — and it is exactly the part that incumbents in pure-software booking tools do not have.

3 — The owned provenance / forensic capability

Sensitive imagery that must be shown to a counterparty is **provenance-stamped so a leaked image is traceable** back to the recipient it was served to — while remaining anonymous to whoever holds it. The mechanism is deliberately private; it is the moat, and it is owned IP. In this public document we state only the capability: a leaked sensitive image can be attributed by VRX, which changes the incentive to leak.

4 — The network, once it exists

Like any trust network, VRX gets more valuable as more vetted operators and channels join: each developer brings agencies, each agency brings agents and buyers. The split architecture is what lets rivals coexist on the same network without exposing each other — which is the precondition for the network to form at all.

> **THE COMPOUNDING**
>
> Any one of these is copyable. Together — the split that must be designed in from the start, a vetting business, owned forensic IP, and a network that benefits from the split — they are a position a fast follower cannot assemble by shipping a feature. That is the investable moat.

SECTION 3 · ARCHITECTURE

The on-chain / off-chain split

One rule governs the whole system: **meaning never touches the chain**. The figure shows what lives where, and the one-way binding between them.

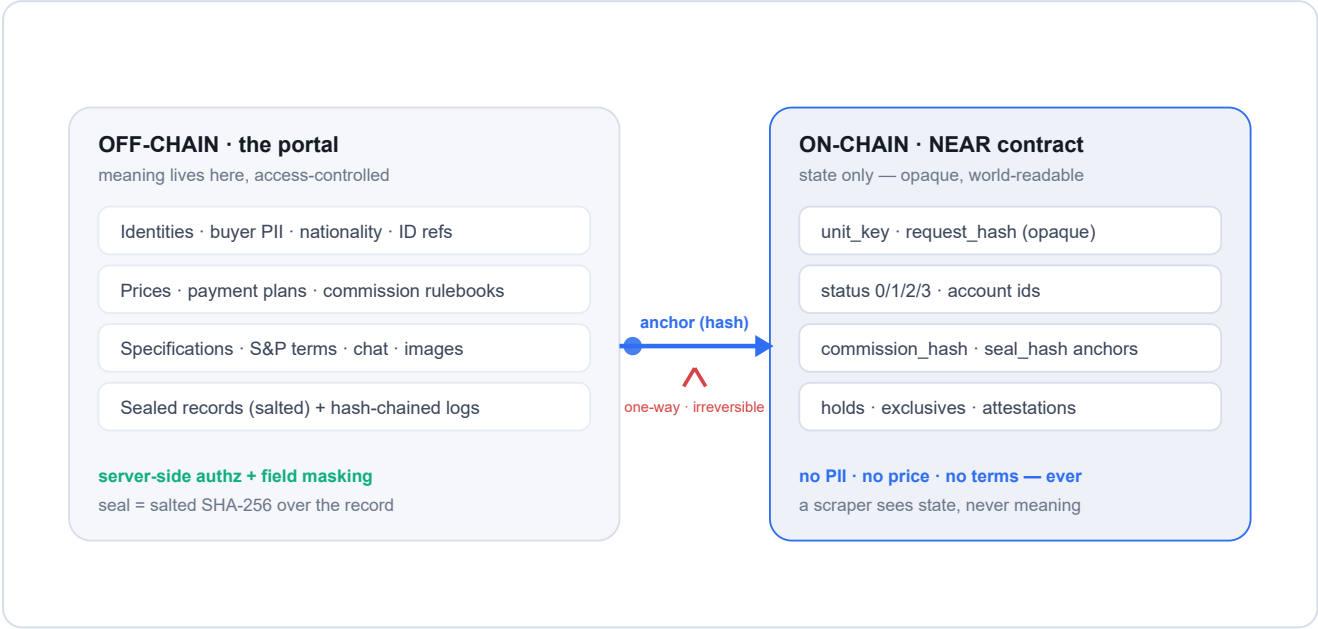

Figure 1 — The split. Off-chain records are sealed; only their hashes are anchored on-chain. The binding is one-way.

WHY ONE-WAY MATTERS

An anchored `seal_hash` lets anyone later prove a specific off-chain record is the one that was committed (re-seal it, compare). It never lets anyone recover the record from the hash. Tamper-evidence without disclosure is the whole trick — and it is what makes the shared truth safe to publish.

SECTION 3 · ARCHITECTURE

One booking, end to end

Follow a single deal from live availability to a confirmed hold, watching where meaning stays and only a hash moves. The contract is deliberately thin; the product value is in orchestrating this flow safely.

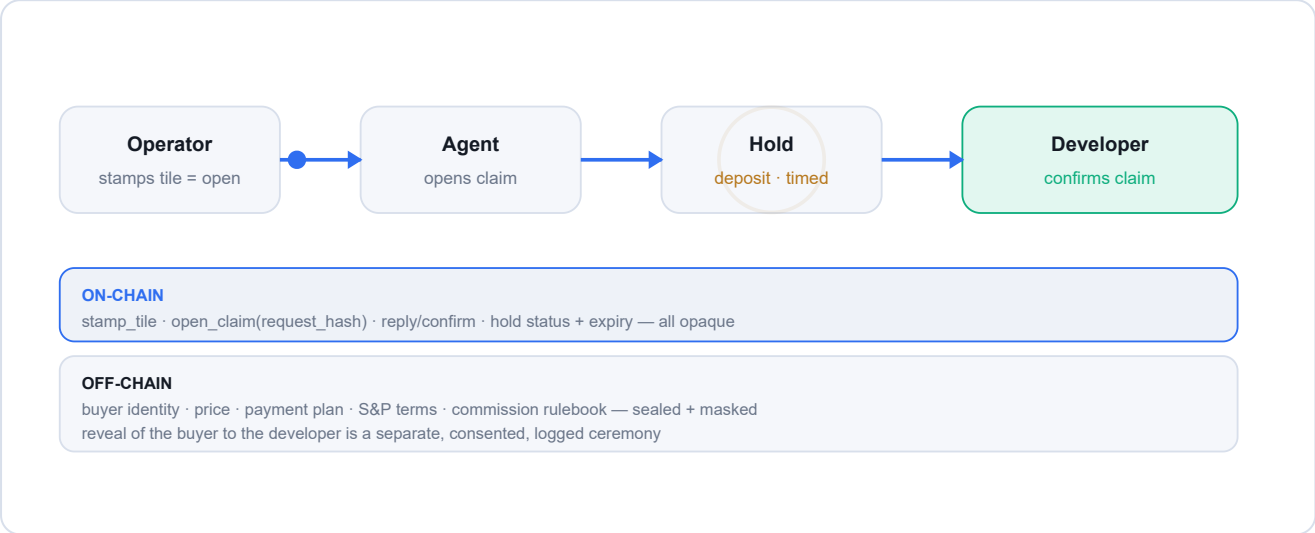

Figure 2 — One booking, end to end. Only opaque keys + state cross into the on-chain lane.

The step sequence

1. Operator stamps a tile → unit `open` (opaque `unit_key`).
2. Agent opens a claim (or burns a booking token) → an opaque `request_hash` anchors the off-chain request; the unit moves to `hold` with a timed expiry.
3. Off-chain: deposit recorded, buyer profile sealed, masked to the developer by default.
4. Developer replies / confirms → state advances; a consented reveal of the buyer is a separate ceremony.
5. On completion the tile is finalized → `done`; expired holds auto-release back to `open`, so scarce capacity is never stranded.

SECTION 4 · PRIVACY

The privacy model — the moat as capability

Two distinct protections, applied per surface: on-chain opacity by construction, and off-chain access control by the server. This is the capability that converts a public chain into infrastructure for confidential commerce.

Protection 1 — on-chain opacity (by construction)

Everything on the contract is an opaque hash (unit, request, seal, commission) plus neutral account ids and status codes. A chain scraper sees "*account X holds an exclusive on hash 07f2…*" — state, never meaning. The building, unit, price, party and terms cannot be derived from the chain. This protection holds by design and needs no further work; it is the half of the moat that is mathematically done.

Protection 2 — off-chain access control (by the server)

The plaintext that carries meaning lives off-chain, protected by **server-side authorization + field-level masking**, not by cryptography. The engineering question for every counterparty-facing surface is: *is this read scoped to a caller entitled to it, and masked server-side before the wire?* A UI blur is theatre; masking happens on the server, so the plaintext never reaches the browser for a masked field. This is where VRX concentrates its engineering, and where the standing audit focuses.

What an outsider can and cannot see

OBSERVER	CAN SEE	CANNOT SEE
Chain scraper	That a reservation/hold/exclusive exists; which account holds it; status + version.	Unit, building, price, party, terms — anything meaningful.
A rival channel	Shared availability (open/held).	Another channel's buyer, price or terms.
Authority-review role	The *vetted state* for oversight.	Private buyer data — the moat extends to the regulator view.

SUPPORTING CAPABILITIES (STATED AT CAPABILITY LEVEL)

Salted seals give tamper-evidence without reversibility; identity-document images are encrypted at rest; the dispute chat is append-only and hash-chained so a back-dated edit is detectable. And sensitive imagery shown to a counterparty is **provenance-stamped so a leaked image is traceable — the mechanism is deliberately private (the moat)**. Each is a control a partner's security team can verify against the submittable audit.

SECTION 5 · NETWORK & BUSINESS MODEL

Vetting & the operator network

VRX is not only a contract — it is the vetting entity and the network operator. Identities enter the system only through VRX; the chain then anchors the fact of a sign-off. This is where the primitive becomes a business.

Owner-gated onboarding

Provisioning a seller (a developer) or an agency is **owner-only**: the contract owner is the vetting identity. KYC / vetting is a human-led off-chain precondition done *before* the on-chain registration call — nothing identifying ever lands on-chain. A developer's captive in-house sales team is simply an org provisioned the same way; there is no special path. The gate is deliberate: an unvetted actor cannot join, which is what makes the shared truth trustworthy to everyone already in it.

The participant roles

ROLE	DOES
Developer(s)	Own the inventory; grant access, mark availability, confirm bookings; may sell direct.
Direct-seller	The developer's own desk selling to a walk-in buyer (not a separate actor).
Agent(s)	Reserve units for buyers on behalf of an agency.
Agency/ies	Manage their agents; work the developers who grant them access.
Buyer	Browses direct-sale inventory and transacts via the desk — a *state*, not a vetted role.
CEO / Approver	Oversees high-stakes financial accountability (an approval trust-dial VRX sets per developer).
Authority Review	Sees the *vetted state* for oversight without ever seeing private data.

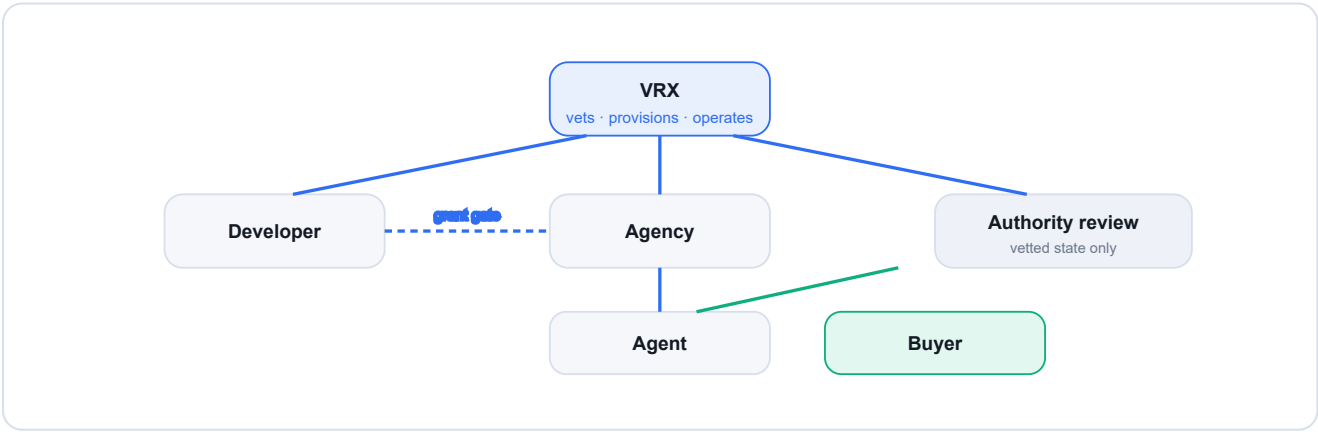

Figure 3 — Roles & trust network. VRX vets the whole system; developers gate agencies; agencies supervise agents; agents serve buyers.

SECTION 5 · NETWORK & BUSINESS MODEL

The primitive vs the business it makes efficient

Two things sit here, and keeping them distinct matters to anyone evaluating the opportunity: VRX the reservation primitive, and Vetted Realty the business that operates the first vetted network on top of it.

VRX	The domain-agnostic primitive — the NEAR contract plus the portal and privacy architecture. It knows nothing about real estate; it is the reusable infrastructure.
VETTED REALTY	The business behind the primitive: the vetting entity and network operator for the real-estate beachhead. It is the first, proving instance of a VRX network.

Why a beachhead, and why this one

Off-plan real estate is chosen deliberately: it is the market where all three failures — double-booking, privacy leakage, circumvention — are simultaneously present, high-value, and painful enough that operators actively look for a fix. Proving the primitive where the problem is sharpest is the credible path: if VRX works for multi-agency off-plan sales, the easier variants of the same shape follow.

The expansion path

Because the contract stores only opaque hashes and never models the asset, moving to a new vertical is not a rebuild — it is a new vetted network, new off-chain field schemas, and a go-to-market motion. The same deployed primitive underwrites each.

PHASE	WHAT IT PROVES	STATUS
1 · Real-estate beachhead	The primitive works for the hardest case; the vetting business is operable.	**built (testnet + sandbox)**
2 · Adjacent high-value assets	Cars, equipment, art — same shape, lighter requirements.	**planned**
3 · Primitive-as-infrastructure	Third-party operators run their own vetted networks on VRX.	**planned**

THE INVESTABLE SHAPE

A business can invest in or partner with Vetted Realty (the operating network, with near-term go-to-market) and/or in VRX the primitive (the longer-horizon infrastructure play). The architecture is built so the first does not foreclose the second: proving the beachhead directly compounds the infrastructure thesis.

Non-circumvention & booking tokens

Two mechanisms keep the network honest and give it an economic rhythm: the buyer stays masked until a deal is firm (so a channel cannot be cut out), and reservation capacity is a scarce, tamper-evident token that cascades down the trust chain.

Non-circumvention

Trust is enforced by **visibility**, not disclosure. An agent holding a booking has the unit off-market; the developer and agency see *who holds it* but not necessarily the private buyer behind it until a consented, sealed reveal. A non-circumvention declaration is sealed as evidence at the reveal request — even if the reveal is later declined — so the introduction is on the tamper-evident trail. This is the mechanism that protects an introducer's commission, which is precisely what gets channels to participate.

The booking-token cascade

VRX issues a developer a scarce quantity of **booking tokens** — reservation capacity. These are handed or sold down the trust chain (developer → agency → agent), with a tamper-evident receipt at each hand-off. An agent holding a token can secure a booking and take a deposit. Capacity is scarce *and* reusable: a released or cancelled token returns up the chain. Tokens surface as "coins" in the wallet.

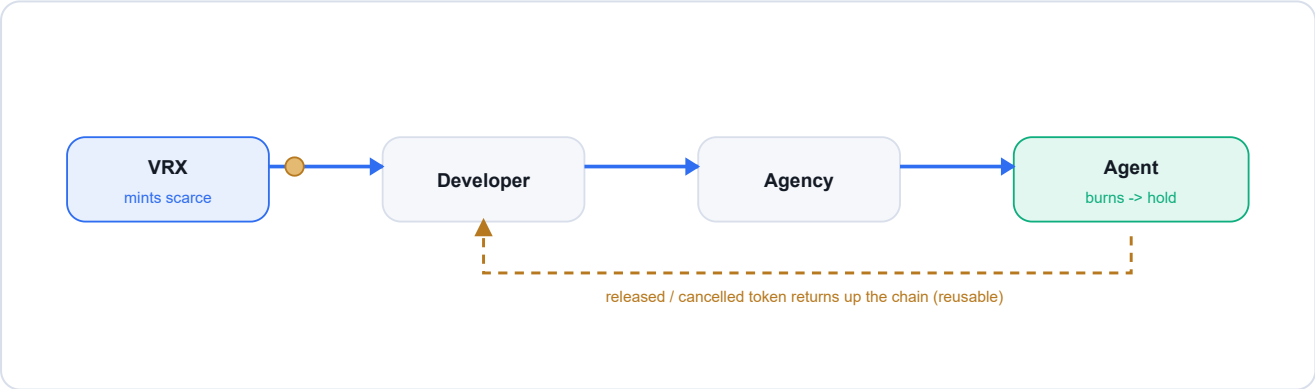

Figure 4 — Booking-token cascade. Scarce, reusable, tamper-evident at each hand-off; a burn opens a hold on-chain.

WHY SCARCITY IS A DESIGN CHOICE, NOT A SALES GIMMICK

Making reservation capacity scarce and reusable is what makes a hold *mean something*: it cannot be created freely, so holding a unit off-market carries a real cost, and releasing it returns capacity to the network. On-chain this is backed by a non-transferable booking token with burn + rebirth, and the exclusive-hold primitive grants one agency the sole right to book a unit for a bounded window that auto-reverts to the shared pool at expiry.

SECTION 6 · THE ECONOMIC LAYER

$VRX — the in-system credit

The economic layer has three objects: the $VRX credit ledger, booking tokens as reservation capacity (above), and commission agreements with a settlement projection. All are privacy-preserving; none puts money terms on-chain.

> **READ THIS FIRST — WHAT $VRX IS, AND IS NOT**
>
> $VRX is an **in-system credit ledger** used to meter and settle activity inside the VRX network. It is *not* a listed or tradeable coin in VRX's story, not a token sale, not a liquid asset, and it is not redeemable for cash. Supply is fixed and treasury-held. Today it is an off-chain ledger; an on-chain NEP-141 fungible-token form is **planned** but does not change what it is. Nothing in this document should be read as an offer of, or a market-value claim about, a token.

The credit, precisely

SUPPLY	Fixed 200,000,000 — non-inflationary, treasury-held.
OPERATIONS	Claim from treasury · send to another account · spend inside the flow.
FORM TODAY	**built** — an off-chain ledger, usable within VRX. Not fiat, not redeemable for cash.
PLANNED	**planned** — the on-chain NEP-141 fungible-token form.

Why a credit at all

A fixed, treasury-held credit gives the network a neutral internal unit to account for usage and settle between participants without each pair needing a bilateral billing relationship. Because it is fixed and non-inflationary, the accounting stays honest: credit moves between accounts, it is not conjured. Keeping it off-chain today is deliberate — the credit model is chain-agnostic, so the on-chain form can be added later without reworking how the network accounts for value.

Booking tokens are distinct from $VRX

A booking token is a unit of *capacity to reserve*, not a credit. It is scarce, cascades down the trust chain, and returns on release (above). Keeping capacity (tokens) and accounting (credit) as separate objects is what lets the network price reservation scarcity independently of how it settles money.

SECTION 6 · THE ECONOMIC LAYER

Commissions, settlement & the revenue model

The last economic object is commission agreements with a settlement projection — and it is here that the revenue model lives. Everything on this sheet is **design**; there is no realised revenue to report.

Commission agreements, privacy-preserving

A commission agreement is anchored on-chain as **only an opaque HMAC anchor** of the off-chain commission rulebook plus a version. The actual percentages, tiers, splits and amounts never appear on-chain. Money compute and owed→paid tracking stay off-chain. On-rail settlement is **planned**; VRX today records payments as a two-sided attestation ledger and **does not move money in-app**. This is the structural reason VRX stays infrastructure rather than a payments institution.

The revenue model — by design

VRX's revenue model is a design, not a track record. It has three plausible rails, each flowing directly from capabilities that are already built:

RAIL	FLOWS FROM	NATURE
Network access / watchlist	Vetted provisioning + the usage toll already in the contract.	Recurring access to the vetted network and its shared availability.
Reservation capacity	The scarce booking-token cascade.	Issuance / sale of reservation capacity down the trust chain.
Settlement rail	Commission anchoring + the payments ledger.	A take on deposit / settlement flow once the on-rail settlement ships (**planned**).

> **HONEST FRAMING OF THE PROJECTION**
>
> Where the product shows a "settlement projection", it is exactly that — a projection computed off-chain from a deal's own terms, not realised revenue and not a forecast of VRX's income. VRX has published **no traction and no revenue figures**, and this document invents none. The claim is that the *model* is coherent and sits on built capabilities — not that it has been monetised yet.

The contract already carries a protocol usage toll + treasury + exempt-list mechanism, so the technical means to meter and collect network usage exists on-chain today; turning that into priced products is the commercial work ahead, done against live operators.

SECTION 7 · STATUS & ROADMAP

What is proven live, and what comes next

Honest status for a diligence read. Built means it runs today on NEAR testnet and in the seeded sandbox; the rest is labelled truthfully. The network is pre-revenue.

Built today

- ✓ On-chain reservation / hold / exclusive / attestation registry, live on NEAR testnet.
- ✓ Role-scoped dashboards for all participant types; browse → book → reserve → hold funnel.
- ✓ Attested off-chain records; commission + settlement *projection*.
- ✓ Booking tokens (scarce, cascading, tamper-evident) shown as "coins".
- ✓ Sale-and-purchase contract authoring (payment plans, packages, concessions, termination terms).
- ✓ Vetting / listing gate; change-notice + oversight; off-chain enforcement.
- ✓ $VRX off-chain credit ledger (claim / send / spend).
- ✓ Provenance-stamped imagery with a two-stage reveal (mechanism deliberately private — the moat).
- ✓ Participation / node-license funnel + a live ecosystem map of the network.

In progress

- Richer agency console (per-agent cards, chat, scheduling / dispatch).
- Real-wallet verified sign-in — the seam is built, currently default-off for the wallet-less demo.

Planned

- Real on-chain settlement rail; a secondary market (ownership transfer); multi-jurisdiction packs.
- $VRX on-chain NEP-141 fungible-token form.
- Determined-attacker-resistant provenance watermark and the read-side image analyzer.
- Vertical expansion beyond real estate (cars, equipment, art).

> **THE HONESTY ANCHOR**
>
> The live portal at `vrx.poolo.org` is a seeded *sandbox* — write actions are simulated so anyone can walk a deal end to end without a wallet. The contract on NEAR testnet (`calculating-hand.testnet`) is the real, verifiable artifact. Path: testnet → mainnet. No known privacy or correctness leak is open; deferred items are deliberate and sequenced behind a dependency, documented in the standing security/privacy audit.

SECTION 8 · LEGAL POSTURE & CONTACT

Legal posture, and how to reach us

The posture is structural and deliberately narrow: VRX facilitates and seals; it does not adjudicate and does not warrant enforceability. That narrowness is a feature for an investor, not a gap.

What VRX is, legally

- ✓ **A facilitator and a sealer.** VRX provides the private shared truth and the tamper-evident record. It records that a reservation, agreement or change happened, and seals it.
- ✓ **Not an adjudicator.** VRX does not decide disputes or determine the outcome of a disagreement between parties. It records the evidence (before/after, who was notified, the sealed declarations) — never the dispute's resolution.
- ✓ **Not a warrantor of enforceability.** VRX does not warrant that any underlying contract is legally enforceable. Parties' own terms and local law govern.
- ✓ **Privacy-by-design.** The architecture itself (opaque on-chain, masked off-chain) is the primary privacy control, not a policy promise layered on afterwards.

> **WHY THE NARROWNESS IS A FEATURE**
>
> By refusing to adjudicate or warrant, VRX stays a neutral infrastructure provider across jurisdictions and asset classes. The sealed, append-only record it produces is designed to be *useful evidence to the parties and their own counsel* — not a substitute for them. This is what keeps the primitive domain-agnostic and multi-jurisdiction-ready (multi-jurisdiction packs are **planned**), and it is what keeps VRX out of the regulatory category it would otherwise fall into by moving money or ruling on disputes.

The oversight view

The Authority-Review role is the legal posture made concrete: an oversight party can confirm the *vetted state* of the system without ever seeing private buyer data. Oversight of process, not exposure of parties — the moat extends even to the regulator view.

In one paragraph, to a cold reader

VRX is the private source of truth for who reserved what. It turns a public blockchain's strength — a tamper-evident, independently-verifiable record — into something usable for confidential commerce by putting *only* opaque proof on-chain and keeping every meaningful detail in a vetted, access-controlled off-chain layer. Real estate proves it; the primitive is domain-agnostic. It is early and pre-revenue, but what it claims to have built, it has built. 312 is not 311.

Contact: `vrx@vettedrealty.com` — the business behind the primitive is Vetted Realty. This is the public Investors & Partners edition; a point-in-time security/privacy audit is available on request to parties under evaluation.
